

# All Coq Rules in One Place

Xiaohong Chen

March 10, 2020

## Abstract

This document summarizes all the proof rules of the Coq proof assistant, as listed in <https://coq.inria.fr/distrib/current/refman/language/cic.html>.

## 1 Syntax

Let us fix a countably infinite set  $V$  of *variables*, denoted  $x, y, \dots$ . Let us fix a countably infinite set  $C$  of *constants*, denoted  $c, d, \dots$ .

**Definition 1.1.** We define the set  $Term$  to be the smallest set that satisfies the following conditions:

1.  $SProp, Prop, Set \in Term$ ;  $Type(i) \in Term$  for every  $i \in \mathbb{N}$ .
2.  $V \subseteq Term$ .
3.  $C \subseteq Term$ .
4. If  $x \in V$  and  $T, U \in Term$ , then  $\forall x:T, U \in Term$ .
5. If  $x \in V$  and  $T, u \in Term$ , then  $\lambda x:T.u \in Term$ .
6. If  $t, u \in Term$ , then  $(tu) \in Term$ , called *application*.
7. If  $x \in V$  and  $t, T, u \in Term$ , then  $\text{let } x := t:T \text{ in } u \in Term$ .

where  $\forall x:T, U$  binds  $x$  to  $U$  and  $\lambda x:T.u$  binds  $x$  to  $u$ . We use  $FV(T) \subseteq V$  to denote the set of free variables in  $T \in Term$ . For  $T, U \in Term$  and  $x \in V$ , we use  $T[U/x]$  to denote the result of substituting  $U$  for  $x$  in  $T$ , where  $\alpha$ -renaming happens implicitly to prevent variable capture.

**Definition 1.2.** We define the set  $Sort = \{SProp, Prop, Set\} \cup \{Type(i) \mid i \in \mathbb{N}\}$ . Note that  $Sort \subseteq Term$ . Elements in  $Sort$  are called *sorts* and denoted as  $s$ , possibly with subscripts.

**Definition 1.3.** A *local assumption* is written  $x:T$ , where  $x \in V$  and  $T \in Term$ . A *local definition* is written  $x := u:T$ , where  $x \in V$  and  $u, T \in Term$ . In both cases, we call  $x$  the *declared variable*. A *local context* is an ordered list of local assumptions and local definitions, such that the declared variables are all distinct. We use  $\Gamma$ , possibly with subscripts, to denote local contexts.

**Notation 1.4.** We use the notation  $[x:T ; y := u:U ; z:V]$  to denote the local context that consists of the local assumption  $x:T$ , the local definition  $y := u:U$  and the local assumption  $z:V$ , with the implicit requirement that  $x, y, z$  are all distinct. The empty local context is written as  $[]$ . Let  $\Gamma$  be a local context. We write  $x \in \Gamma$  to mean that  $x$  is declared in  $\Gamma$ . We write  $(x:T) \in \Gamma$  to mean that the local assumption  $x:T$  is in  $\Gamma$ , or that the local definition  $x := u:T$  is in  $\Gamma$  for some  $u \in Term$ . We write  $(x := u:T) \in \Gamma$  to mean that the local definition  $x := u:T$  is in  $\Gamma$ . We write  $\Gamma :: (x:T)$  to denote the local context that enriches  $\Gamma$  with  $x:T$ , with the implicit requirement that  $x \notin \Gamma$ . Similarly, we write  $\Gamma :: (x := u:T)$  to denote the local context that enriches  $\Gamma$  with  $x := u:T$ , with the implicit requirement that  $x \notin \Gamma$ . We write  $\Gamma_1 ; \Gamma_2$  to mean the local context obtained by concatenating  $\Gamma_1$  and  $\Gamma_2$ , with the implicit requirement that all variables declared in  $\Gamma_2$  are not declared in  $\Gamma_1$ .

**Definition 1.5.** Global context ...
